#### DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

#### **VISION**

To provide a congenial ambience for individuals to develop and blossom as academically superior, socially conscious and nationally responsible citizens.

#### **MISSION**

M1: Impart high quality computer knowledge to the students through a dynamic scholastic environment wherein they learn to develop technical, communication and leadership skills to bloom as a versatile professional.

**M2:** Develop life-long learning ability that allows them to be adaptive and responsive to the changes in career, society, technology, and environment

**M3:** Build student community with high ethical standards to undertake innovative research and development in thrust areas of national and international needs.

**M4:** Expose the students to the emerging technological advancements for meeting the demands of the industry.

#### PROGRAMME EDUCATIONAL OBJECTIVES (PEO)

PEO	PEO STATEMENTS
PEO1	To prepare graduates with potential to get employed in the right role and/or become entrepreneurs to contribute to the society.
PEO2	To provide the graduates with the requisite knowledge to pursue higher education and carry out research in the field of Computer Science and Engineering.
PEO3	To equip the graduates with skills required to stay motivated and adapt to dynamically changing world so as to remain successful in their career.
PEO4	To train the graduates to communicate effectively, work collaboratively and exhibit levels of professionalism and ethical responsibility.

#### **COURSE OBJECTIVES**

- To provide the most comprehensive concept of neural networks in the engineering perspective
- To understand the important design concepts of neural architectures in different applications
- To acquaint student with various computing algorithms in FLNN using software tools.
- To understand operation of basic elements in fuzzy logic and neural network through simulation.

#### LIST OF EXERCISES

- 1. Write a program to implement the concept of Perceptrons.
- 2. Write a program to simulate Back-Propagation Neural Networks.
- 3. Write a program to implement the Radial Basis Function Neural Networks.
- 4. Write a program to implement a real world application using Support Vector Machine.
- 5. Write a program to design a Self Organizing Map for an application.
- 6. Write a program to develop fuzzy membership functions and fuzzy set properties.
- 7. Write a program to develop logic for fuzzy relations.
- 8. Write a program to verify logic using fuzzy relations.
- 9. Write a program to design a fuzzy controller systems using fuzzy tool of Matlab.
- 10. Develop an application using NN/Fuzzy logic.

#### **COURSE OUTCOMES**

At the end of this course, the students will be able to

- 1. Demonstrate basic concepts fuzzy logic and neural network through simulation.
- 2. Develop the logic given in problem statement using operations in fuzzy logic and basics of toolbox studied.
- 3. Demonstrate an ability to listen and answer viva questions related to programming skills for solving real world problems in Computer Science and Engineering.

Ex. No. 1(a) Perceptron Algorithm on Randomly Generated Dataset

Date:

Aim:

To implement perceptron algorithm using Python programming.

**Perceptron Learning:** 

The <u>Perceptron algorithm</u> is a two-class (binary) classification machine learning algorithm. It is the simplest type of neural network model. It consists of a single node or neuron that takes a row of data as input and predicts a class label. This is achieved by calculating the weighted sum of the inputs and a bias (set to 1). The weighted sum of the input of the model is called the activation given as

**Activation** = Weights \* Inputs + Bias

If the activation is above 0.0, the model will output 1.0; otherwise, it will output 0.0 given as:

**Predict 1**: If Activation > 0.0

**Predict 0**: If Activation  $\leq 0.0$ 

The Perceptron is a linear classification algorithm. This means that it learns a decision boundary that separates two classes using a line (called a hyperplane) in the feature space. The coefficients of the model are referred to as input weights and are trained using the stochastic gradient descent optimization algorithm.

Examples from the training dataset are shown to the model one at a time, the model makes a prediction, and error is calculated. The weights of the model are then updated to reduce the errors for the example. This is called the Perceptron update rule. This process is repeated for all examples in the training dataset, called an <u>epoch</u>. This process of updating the model using examples is then repeated for many epochs.

Model weights are updated with a small proportion of the error each batch, and the proportion is controlled by a hyperparameter called the learning rate, typically set to a small value as shown below.

weights(t + 1) = weights(t) + learning rate \* (expected i – predicted ) \* input i

Training is stopped when the error made by the model falls to a low level or no longer improves, or a maximum number of epochs is performed. The initial values for the model weights are set to small random values.

1

#### Algorithm:

- 1. Set a threshold value
- 2. Multiply all inputs with their weights
- 3. Sum all the results
- 4. Activate the output and return true if greater than the threshold.

#### **Program:**

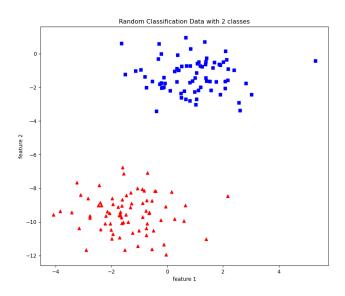

```
import numpy as np
from sklearn import datasets
import matplotlib.pyplot as plt
X, y = datasets.make blobs(n samples=150,n features=2, centers=2, cluster std=1.05,
                 random state=2)
#Plotting
fig = plt.figure(figsize=(10,8))
plt.plot(X[:, 0][y == 0], X[:, 1][y == 0], 'r^{\prime})
plt.plot(X[:, 0][y == 1], X[:, 1][y == 1], 'bs')
plt.xlabel("feature 1")
plt.ylabel("feature 2")
plt.title('Random Classification Data with 2 classes')

# **Output:**

# **Result:**

Thus a python program has been written and executed to implement perceptron algorithm.

#### Ex. No. 1(b) Implementation of OR Gate using Perceptron Algorithm

Date:

Aim:

To implement OR gate using perceptron algorithm in Python programming.

#### **Program:**

```
import numpy as np
class Perceptron:
  def init (self) -> None:
     self.weights = np.zeros((2, 1))
     self.bias = 0
  def predict(self, x: np.array) -> np.array:
     return np.where(np.dot(x, self.weights) + self.bias > 0, 1, 0)
  def fit(self, x: np.array, y: np.array, epoch:int = 100, learning_rate: float= 0.1) -> None:
     for in range(epoch):
       for x_i, y_i in zip(x, y):
          y hat = self.predict(x i).squeeze()
          self.weights += learning_rate * (y_i - y_hat) * x_i.reshape(-1, 1)
          self.bias += learning rate * (y i - y hat)
  def score(self, x: np.array, y: np.array) -> float:
     y_hat = self.predict(x).squeeze()
     return np.mean(y_hat == y)
if name _ == '__main__':
  X = \text{np.array}([[0, 0], [0, 1], [1, 0], [1, 1]])
  y = np.array([0, 1, 1, 1])
  perceptron = Perceptron()
  print("OR Gate: ")
  for x, y_i in zip(X, y):
     print(x, y i)
  print("Initial Weights:")
```

```
print(perceptron.weights, perceptron.bias)
  perceptron.fit(X, y, epoch=3)
  print("Trained Weights:")
  print(perceptron.weights, perceptron.bias)
  print("OR Gate(predicted): ")
  for x in X:
     print(x, perceptron.predict(x))
  print("Accuracy:", perceptron.score(X, y))
Output:
OR Gate:
[0 0] 0
[0\ 1]\ 1
[1 0] 1
[1 1] 1
Initial Weights:
[[0.]]
[0.]]0
Trained Weights:
[[0.1]]
[0.1]] 0.0
OR Gate(predicted):
[0\ 0]\ [0]
[0 1] [1]
[10][1]
[1 1] [1]
```

#### **Result:**

Accuracy: 1.0

Thus the python program to implement OR gate with perceptron algorithm is successfully executed and the output is verified.

#### Ex. No. 2 BACKPROPAGATION NEURAL NETWORK

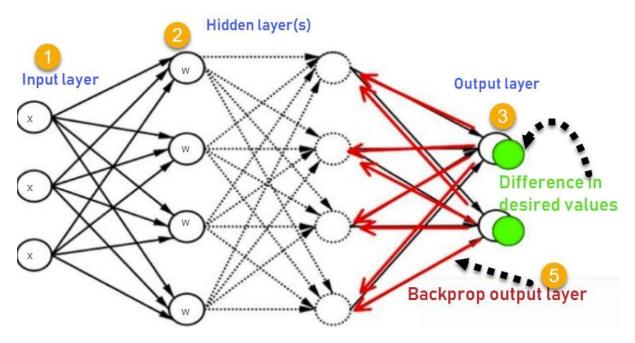

Date:

#### Aim:

To implement Backpropagation Neural Network using Python programming.

#### Algorithm:

The Back propagation algorithm in neural network computes the gradient of the loss function for a single weight by the chain rule. It efficiently computes one layer at a time, unlike a native direct computation

Consider the following Back propagation Neural Network.

- 1. Inputs X, arrive through the preconnected path.
- 2. Input is modeled using real weights W. The weights are usually randomly selected.
- 3. Calculate the output for every neuron from the input layer, to the hidden layers, to the output layer.
- 4. Calculate the error in the outputsError= Actual Output Desired Output
- 5. Travel back from the output layer to the hidden layer to adjust the weights such that the error is decreased.

Keep repeating the process until the desired output is achieved.

#### Program:

```
import numpy as np

#### **Result:**

Thus a python program has been written and executed to implement Backpropagation Neural Network model.

#### Ex. No. 3 RADIAL BASIS FUNCTION NEURAL NETWORK

Date:

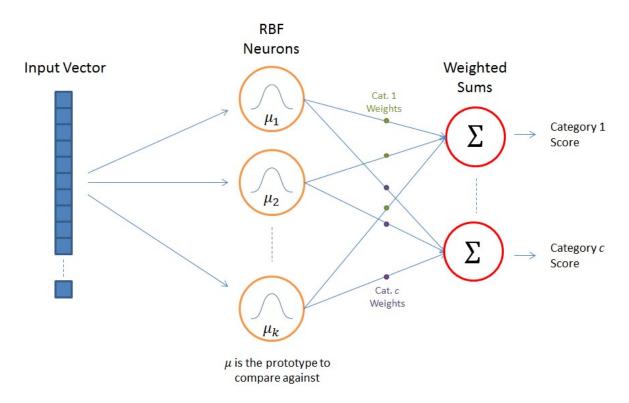

#### Aim:

To implement Radial Basis Function Neural Network using Python Programming.

#### **Radial Basis Function Neural Network (RBFNN):**

A Radial Basis Function Network is a particular type of neural network. In this article, An RBFNN performs classification by measuring the input's similarity to examples from the training set. Each RBFNN neuron stores a "prototype", which is just one of the examples from the training set. When we want to classify a new input, each neuron computes the Euclidean distance between the input and its prototype. If the input more closely resembles the class A prototypes than the class B prototypes, it is classified as class A.

#### **RBFNN Architecture:**

The above figure shows the typical architecture of an RBF Network. It consists of an input vector, a layer of RBF neurons, and an output layer with one node per category or class of data.

#### The Input Vector

The input vector is the *n*-dimensional vector that you are trying to classify. The entire input vector is shown to each of the RBF neurons.

#### The RBF Neurons

Each RBF neuron stores a "prototype" vector which is just one of the vectors from the training set. Each RBF neuron compares the input vector to its prototype, and outputs a value between 0 and 1 which is a measure of similarity. If the input is equal to the prototype, then the output of that RBF neuron will be 1. As the distance between the input and prototype grows, the response falls off exponentially towards 0. The shape of the RBF neuron's response is a bell curve, as illustrated in the network architecture diagram. The neuron's response value is also called its "activation" value. The prototype vector is also often called the neuron's "center", since it's the value at the center of the bell curve.

#### **The Output Nodes**

The output of the network consists of a set of nodes, one per category that we are trying to classify. Each output node computes a sort of score for the associated category. Typically, a classification decision is made by assigning the input to the category with the highest score.

The score is computed by taking a weighted sum of the activation values from every RBF neuron. By weighted sum we mean that an output node associates a weight value with each of the RBF neurons, and multiplies the neuron's activation by this weight before adding it to the total response.

Because each output node is computing the score for a different category, every output node has its own set of weights. The output node will typically give a positive weight to the RBF neurons that belong to its category, and a negative weight to the others.

#### **RBF** Neuron Activation Function

Each RBF neuron computes a measure of the similarity between the input and its prototype vector (taken from the training set). Input vectors which are more similar to the prototype return a result closer to 1. There are different possible choices of similarity functions, but the most popular is based on the Gaussian. Below is the equation for a Gaussian with a one-dimensional input.

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

Where x is the input, mu is the mean, and sigma is the standard deviation. This produces the familiar bell curve shown below, which is centered at the mean, mu (in the below plot the mean is 5 and sigma is 1). The RBF neuron activation function is slightly different, and is typically written as:

$$\varphi(x) = e^{-\beta||x-\mu||^2}$$

In the Gaussian distribution,  $\mu$  refers to the mean of the distribution. Here, it is the prototype vector which is at the center of the bell curve.

#### **Program:**

#### Ex. No. 4(a) SUPPORT VECTOR MACHINE ON SOCIAL MEDIA ADS DATASET

Date:

#### Aim:

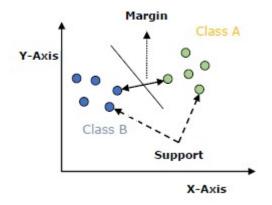

To implement a Support Vector Machine on Social Media Ads dataset using Python programming.

#### **Support Vector Machine(SVM):**

Support vector machines (SVMs) are powerful yet flexible supervised machine learning algorithms that are used both for classification and regression. But generally, they are used in classification problems. In the 1960s, SVMs were first introduced but later they got refined in 1990. SVMs have their unique way of implementation as compared to other machine learning algorithms. Lately, they are extremely popular because of their ability to handle multiple continuous and categorical variables.

#### **Working of SVM**

An SVM model is basically a representation of different classes in a hyperplane in multidimensional space. The hyperplane will be generated iteratively by SVM so that the error can be minimized. The goal of SVM is to divide the datasets into classes to find a maximum marginal hyperplane (MMH).

The following are important concepts in SVM:

- **Support Vectors** Datapoints that are closest to the hyperplane are called support vectors. Separating lines will be defined with the help of these data points.
- **Hyperplane** As we can see in the above diagram, it is a decision plane or space which is divided between a set of objects having different classes.
- Margin It may be defined as the gap between two lines on the closet data points of
  different classes. It can be calculated as the perpendicular distance from the line to the
  support vectors. A large margin is considered as a good margin and a small margin is
  considered as a bad margin.

The main goal of SVM is to divide the datasets into classes to find a maximum marginal hyperplane (MMH) and it can be done in the following two steps –

- First, SVM will generate hyperplanes iteratively that segregate the classes in the best way.
- Then, it will choose the hyperplane that separates the classes correctly.

weighted avg	0.96	0.96	0.96	50

# **Result:**

Thus a python program to implement XOR gate using Support Vector Machine has been written and executed.

#### **Ex. No. 5**

#### **SELF-ORGANIZING MAP**

Date:

#### Aim:

To implement a Self-Organizing Map using Python Programming.

#### **Self-Organizing Maps:**

It is a type of Artificial Neural Network which is also inspired by biological models of neural systems from the 1970s. It follows an unsupervised learning approach and trained its network through a competitive learning algorithm. SOM is used for clustering and mapping (or dimensionality reduction) techniques to map multidimensional data onto lower-dimensional which allows people to reduce complex problems for easy interpretation. SOM has two layers, one is the Input layer and the other one is the Output layer. The architecture of the Self Organizing Map with two clusters and n input features of any sample is given below:

#### **Working Principle of SOM:**

Let's say an input data of size (m, n) where m is the number of training examples and n is the number of features in each example. First, it initializes the weights of size (n, C) where C is the number of clusters. Then iterating over the input data, for each training example, it updates the winning vector (weight vector with the shortest distance (e.g. Euclidean distance) from training example). Weight updation rule is given by:

$$w_{ij} = w_{ij}(old) + alpha(t) * (x_i^k - w_{ij}(old))$$

where alpha is a learning rate at time t, j denotes the winning vector, i denotes the  $i^{th}$  feature of training example and k denotes the  $k^{th}$  training example from the input data. After training the SOM network, trained weights are used for clustering new examples. A new example falls in the cluster of winning vectors.

#### Algorithm:

- 1. Weight initialization
- 2. For 1 to N number of epochs
- 3. Select a training example
- 4. Compute the winning vector
- 5. Update the winning vector
- 6. Repeat steps 3, 4, 5 for all training examples.
- 7. Clustering the test sample

# **Program:** import math class SOM: # Function here computes the winning vector by Euclidean distance def winner( self, weights, sample ): D0 = 0D1 = 0for i in range(len(sample)): D0 += (sample[i] - weights[0][i]) \*\* 2D1 += (sample[i] - weights[1][i]) \*\* 2 If D0 < D1: return 0 return 1 # Else Return 1 # Function here updates the winning vector def update(weights, sample, j, alpha): for i in range(len(sample)): weights[j][i] = weights[j][i] + alpha \* (sample[i] - weights[j][i]) return weights # Driver code if name == " main ": # Training Examples ( m, n ) T = [[1, 1, 0, 0], [0, 0, 0, 1], [1, 0, 0, 0], [0, 0, 1, 1]]m, n = len(T), len(T[0])# weight initialization (n, C) weights = [ [ 0.2, 0.6, 0.5, 0.9 ], [ 0.8, 0.4, 0.7, 0.3 ] ]# training

ob = SOM()

epochs = 3

```
alpha = 0.5
for i in range( epochs ) :
    for j in range( m ) :
        # training sample
        sample = T[j]
        # Compute winner vector
        J = ob.winner( weights, sample )
        # Update winning vector
        weights = ob.update( weights, sample, J, alpha )
# classify test sample
s = [ 1, 1, 0, 1 ]
J = ob.winner( weights, s )
print( "Test Sample s belongs to Cluster : ", J )
print( "Trained weights : ", weights )
```

#### **Output:**

```
Test sample s belongs to: 1
```

Trained weights: [[0.003125, 0.009375, 0.6640625, 0.9984375], [0.996875, 0.334375, 0.0109375, 0.0046875]]

#### **Result:**

Thus a python program has been written and executed to implement Self Organizing Map.

#### Ex. No. 6

#### **FUZZY SET OPERATIONS**

Date:

Aim:

To write a MATLAB program to find the algebraic sum, algebraic subtraction, algebraic product, bounded sum, bounded subtraction, and bounded product of two fuzzy sets.

#### Algorithm:

- 1. Read the values of the two fuzzy sets.
- 2. Perform the algebraic sum operation by,

$$A + B = (a + b) - (a * b)$$

3. Perform the algebraic subtraction operation by,

$$A - B = (a + b)$$
 where b'= 1- b

4. Perform the algebraic product operation by,

$$A * B = (a * b)$$

5. Perform the bounded sum operation by,

$$A \oplus B = \min [1, (a + b)]$$

6. Perform bounded subtraction operation by,

$$A \ominus B = max [0, (a - b)]$$

7. Perform bounded product operation by,

$$A \odot B = \max [0, (a + b - 1)]$$

8. Display the results

#### **Program:**

a= input('Enter the fuzzy set a' )

b= input('Enter the fuzzy set b')

$$c = a + b$$

$$d=a.*b$$

$$as = c - d$$

$$e = 1 - b$$

$$ad = a + e$$

$$f=a-b$$

$$bs = min(1, c)$$

```
bd= max (0, f)

g= c - 1

bp= max (0,g)

disp('The algebraic sum')

disp(as)

disp('The algebraic difference')

disp(ad)

disp('The algebraic product')

disp(d)

disp('The bounded sum')

disp(bs)

disp('The bounded difference')

disp (bd)

disp('The bounded product')

disp(bp)
```

#### **Output:**

Enter fuzzy set a [1 0.5]
Enter fuzzy set b [0.4 0.2]
The algebraic sum
[1.0000 0.6000]
The algebraic difference
[1 0.9000]
The algebraic product
[0.4000 0.1000]
The bounded sum
[1.0000 0.7000]
The bounded difference
[0.6000 0.3000]
The bounded product
[0.4000 0]

#### **Result:**

Thus, a MATLAB program to perform simple fuzzy set operations has been executed and successfully verified.

#### **Ex. No. 7**

#### **FUZZY SET PROPERTIES**

Date:

Aim:

To write a program in MATLAB to verify the properties of fuzzy sets.

#### Algorithm:

To Verify the following Fuzzy Set Properties:

#### **Commutative property**

$$\underline{\mathbf{A}} \cup \underline{\mathbf{B}} = \underline{\mathbf{B}} \cup \underline{\mathbf{A}}$$

$$\underline{\mathbf{A}} \cap \underline{\mathbf{B}} = \underline{\mathbf{B}} \cap \underline{\mathbf{A}}$$

**Associative property** 

$$(\underline{A} \cup \underline{B}) \cup \underline{C} = \underline{A} \cup (\underline{B} \cup \underline{C})$$

$$(\underline{A} \cap \underline{B}) \cap \underline{C} = \underline{A} \cap (\underline{B} \cap \underline{C})$$

**Distributive property** 

$$\underline{A} \cup (\underline{B} \cap \underline{C}) = (\underline{A} \cup \underline{B}) \cap (\underline{A} \cup \underline{C})$$

$$\underline{A} \cap (\underline{B} \cup \underline{C}) = (\underline{A} \cap \underline{B}) \cup (\underline{A} \cap \underline{C})$$

**Absorption property** 

$$\underline{\mathbf{A}} \cup (\underline{\mathbf{A}} \cap \underline{\mathbf{C}}) = \underline{\mathbf{A}}$$

$$\underline{\mathbf{A}} \cap (\underline{\mathbf{A}} \cup \underline{\mathbf{C}}) = \underline{\mathbf{A}}$$

**Idempotency property** 

$$\underline{\mathbf{A}} \cup \underline{\mathbf{A}} = \underline{\mathbf{A}}$$

$$\underline{\mathbf{A}} \cap \underline{\mathbf{A}} = \underline{\mathbf{A}}$$

De Morgan's law

$$(\underline{\mathbf{A}} \cup \underline{\mathbf{B}})' = \underline{\mathbf{A}}' \cap \underline{\mathbf{B}}'$$

$$(\underline{A} \cap \underline{B})' = \underline{A'} \cup \underline{B}'$$

**Identity property** 

$$\underline{\mathbf{A}} \cup \mathbf{\phi} = \underline{\mathbf{A}}$$

$$\underline{\mathbf{A}} \cap \mathbf{X} = \underline{\mathbf{A}}$$

**Axiom of Excluded Middle** 

$$\underline{\mathbf{A}} \cap \mathbf{\phi} = \mathbf{\phi}$$

**Axiom of Contradiction** 

$$A \cup X = X$$

#### Ex. No. 8 FUZZY MEMBERSHIP FUNCTIONS

Date:

Aim:

To write a program in MATLAB to plot triangular, trapezoidal and bell shaped membership functions.

### Algorithm:

- 1. Set the limits of x-axis.
- 2. Calculate y using trimf() function with three parameters for triangular membership function.
- 3. Calculate y using trapmf() function with four parameters for trapezoidal membership function.
- 4. Calculate y using gbellmf() function with three parameters for bell shaped membership function.
- 5. Plot x and y values.

### **Program:**

```
%Triangular membership function

x=(0.0:1.0:10.0)';

y1= trimf(x, [1 3 5]);

subplot(311)

plot(x,[y1]);

%Trapezoidal membership function

x=(0.0:1.0:10.0)';

y1= trapmf(x, [1 3 5 7]);

subplot(312)

plot(x, [y1]);

%Bell-shaped membership function

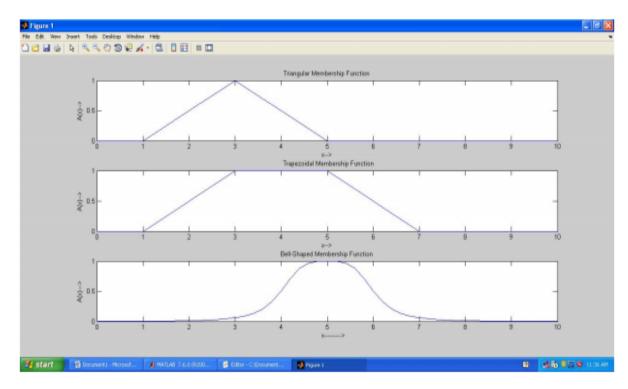

x=(0.0:0.2:10.0);

y1=gbellmf (x,[3 57]);

subplot(313)

plot(x, [y1]);
```

## **Output:**

### **Result:**

Thus, the MATLAB program for plotting membership functions has been executed successfully and the output is verified.

### Ex. No. 9 FUZZY INFERENCE SYSTEM

Date:

Aim:

To implement a Fuzzy Inference System (FIS) using MATLAB.

**Inputs:** Temperature and Cloud Cover

**Temperature:** {Freeze, Cool, Warm and Hot}

**Cloud Cover:** {Sunny, Partly Cloud, and Overcast}

Output: Speed

**Speed**: {Fast and Slow}

#### **Rules:**

 If cloud cover is Sunny and temperature is warm, then drive Fast Sunny (Cover) and Warm (Temp) -> Fast (Speed)

2. If the cloud cover is cloudy and the temperature is cool, then drive Slow Cloudy (Cover) and Cool (Temp) -> Slow (Speed)

#### **Procedure:**

- 1. Go to the command window in Matlab and type fuzzy.
- 2. Now, a new Fuzzy Logic Designer window will be opened.
- 3. Input / Output Variable
  - a. Go to Edit Window and click Add variable.
  - b. As per our requirements create two input variables, Temperature and Cloud Cover.
  - c. Create one output variable, Speed.

#### 4. Temperature:

- a. Double click the Temperature input variable in the Fuzzy Logic Designer window.
- b. A new window will be opened and remove all the Membership Functions.
- c. Now, Go to Edit, Click Add MFs and select the 4 Parameters for Temperature Class.
- d. Change the following fields as mentioned data in the given below table.

Inputs : Temperature   Freezing, Cool, Warm and Hot				
MF1:	MF2:	MF3:	MF4:	
Range : [0 110]	Range : [0 110]	Range : [0 110]	Range : [0 110]	
Name: Freezing	Name: Cool	Name : Warm	Name: Hot	
Type :trapmf	Type :trimf	Type :trimf	Type :trapmf	
Parameter [0 0 30 50]	Parameter [30 50 70]	Parameter [50 70 90]	Parameter [70 90 110 110]	

5. Similarly, add the datas to the Cloud Cover variables and Speed variables.

### 6. Cloud Cover:

Inputs: Cloud Cover 🛘 Sunny, Partly Cloud and Overcast				
MF1:	MF2:	MF3:		
Range : [0 100]	Range : [0 100]	Range : [0 100]		
Name: Sunny	Name: Partly Cloud	Name : Overcast		
Type :trapmf	Type :trimf	Type :trapmf		
Parameter [0 0 20 40]	Parameter [20 50 80]	Parameter [60 80 100]		

# 7. Speed:

Output : Speed   Slow and Fast			
MF1:	MF2:		
Range : [0 100]	Range : [0 100]		
Name: Slow	Name : Fast		
Type :trapmf	Type :trapmf		

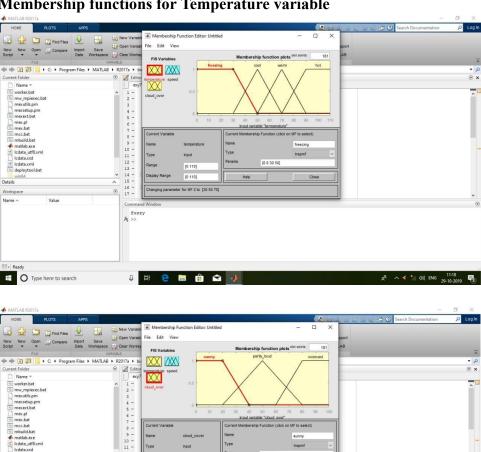

Parameter [0 0 25 75]	Parameter [25 75 100 100]

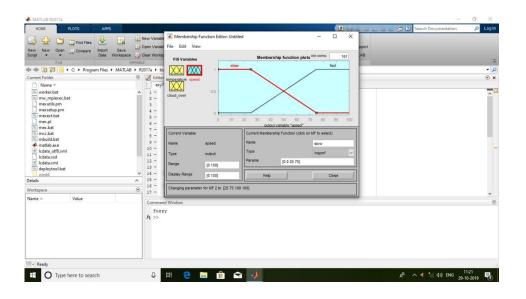

- Goto Rules: Edit 🛘 Rules
- 9. Add the Rules
  - Rule-1: Sunny (Cover) and Warm (Temp) -> Fast (Speed)
  - Rule-2: Cloudy (Cover) and Cool (Temp) -> Slow (Speed)
  - 10. Go to view □ Rules
- 11. Exit.

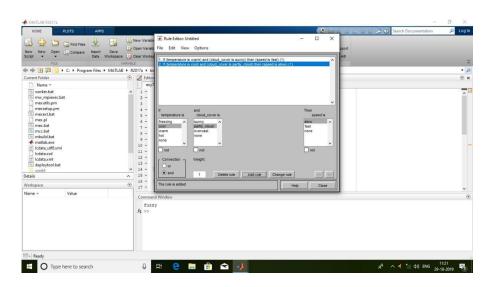

### **Output:**

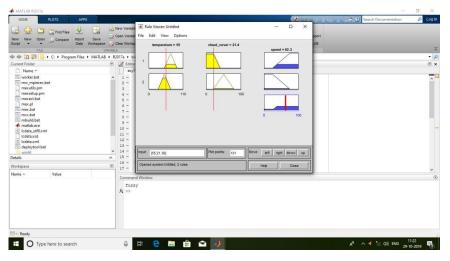

Type here to search

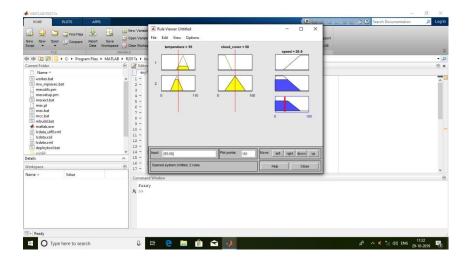

### **Membership functions for Temperature variable**

# **Result:**

Thus a Fuzzy Inference System is successfully executed using MATLAB.

### Ex. No. 10 Defuzzification Methods

#### Date:

#### Aim:

To write a program in Python to implement defuzzification methods using fuzzy toolbox.

### Algorithm:

- 1. Import numpy, matplotlib and skfuzzy packages.
- 2. Trapezoidal membership function on range [0, 1] using trapmf function with four parameters.
- 3. Defuzzify trapezoidal membership function by using fuzzy toolbox functions centroid, bisector, mom, Som and lom.
- 4. Plot the defuzzified values using matplotlib.

### **Program:**

```
import numpy as np
import matplotlib.pyplot as plt
import skfuzzy as fuzz

# Generate trapezoidal membership function on range [0, 1]

x = np.arange(0, 5.05, 0.1)

mfx = fuzz.trapmf(x, [2, 2.5, 3, 4.5])

# Defuzzify this membership function five ways

defuzz_centroid = fuzz.defuzz(x, mfx, 'centroid')

defuzz_bisector = fuzz.defuzz(x, mfx, 'bisector')

deuzz_mom = fuzz.defuzz(x, mfx, 'mom')

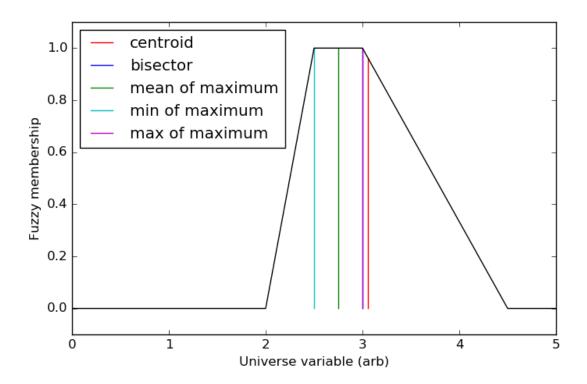

defuzz_som = fuzz.defuzz(x, mfx, 'som')

defuzz_lom = fuzz.defuzz(x, mfx, 'lom')
```

```
# Collect info for vertical lines
labels = ['centroid', 'bisector', 'mean of maximum', 'min of maximum', 'max of maximum']
xvals = [defuzz_centroid, defuzz_bisector, defuzz_mom, defuzz_som, defuzz_lom]
colors = ['r', 'b', 'g', 'c', 'm']
ymax = [fuzz.interp membership(x, mfx, i) for i in xvals]
# Display and compare defuzzification results against membership function
plt.figure(figsize=(8, 5))
plt.plot(x, mfx, 'k')
for xv, y, label, color in zip(xvals, ymax, labels, colors):
  plt.vlines(xv, 0, y, label=label, color=color)
plt.ylabel('Fuzzy membership')
plt.xlabel('Universe variable (arb)')
plt.ylim(-0.1, 1.1)
plt.legend(loc=2)
```

plt.show()

# **Output:**

### **Result:**

Thus, the Python program for implementing defuzzification methods has been executed successfully and the output is verified.

### Ex. No. 11 THE TIPPING PROBLEM

Date:

#### Aim:

To develop a fuzzy controller for the Tipping problem using Python programming.

### The Tipping Problem:

The 'tipping problem' is commonly used to illustrate the power of fuzzy logic principles to generate complex behavior from a compact, intuitive set of expert rules.

A fuzzy control system is created to model how you might choose to tip at a restaurant. When tipping, the service and food quality are considered and rated between 0 and 10. A tip of between 0 and 25% is suggested.

#### **Problem Formulation:**

- \* Antecednets (Inputs)
  - `service`
    - \* Universe (ie, crisp value range): How good was the service of the wait staff, on a scale of 0 to 10?
    - \* Fuzzy set (ie, fuzzy value range): poor, acceptable, amazing
  - `food quality`
    - \* Universe: How tasty was the food, on a scale of 0 to 10?
    - \* Fuzzy set: bad, decent, great
- \* Consequents (Outputs)
  - 'tip'
    - \* Universe: How much should we tip, on a scale of 0% to 25%
    - \* Fuzzy set: low, medium, high
- \* Rules
  - IF the \*service\* was good \*or\* the \*food quality\* was good, THEN the tip will be high.
  - IF the \*service\* was average, THEN the tip will be medium.
  - IF the \*service\* was poor \*and\* the \*food quality\* was poor THEN the tip will be low.
- \* Usage
  - If I tell this controller that I rated:
    - \* the service as 9.8, and
    - \* the quality as 6.5,
  - it would recommend I leave:
    - \* a 20.2% tip.

#### Creating the Tipping Controller Using the skfuzzy control API

import numpy as np

import skfuzzy as fuzz

```
# New Antecedent/Consequent objects hold universe variables and membership
# functions
quality = ctrl.Antecedent(np.arange(0, 11, 1), 'quality')
service = ctrl.Antecedent(np.arange(0, 11, 1), 'service')
tip = ctrl.Consequent(np.arange(0, 26, 1), 'tip')
# Auto-membership function population is possible with .automf(3, 5, or 7)
quality.automf(3)
service.automf(3)
# Custom membership functions can be built interactively with a familiar,
# Pythonic API
tip['low'] = fuzz.trimf(tip.universe, [0, 0, 13])
tip['medium'] = fuzz.trimf(tip.universe, [0, 13, 25])
tip['high'] = fuzz.trimf(tip.universe, [13, 25, 25])
# You can see how these look with .view()
quality['average'].view()
service.view()
tip.view()
rule1 = ctrl.Rule(quality['poor'] | service['poor'], tip['low'])
rule2 = ctrl.Rule(service['average'], tip['medium'])
rule3 = ctrl.Rule(service['good'] | quality['good'], tip['high'])
rule1.view()
tipping ctrl = ctrl.ControlSystem([rule1, rule2, rule3])
```

tipping = ctrl.ControlSystemSimulation(tipping ctrl)

# Pass inputs to the ControlSystem using Antecedent labels with Pythonic API

# Note: if you like passing many inputs all at once, use .inputs(dict of data)

tipping.input['quality'] = 6.5

tipping.input['service'] = 9.8

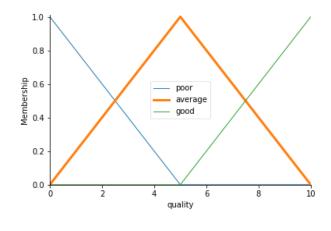

# Crunch the numbers

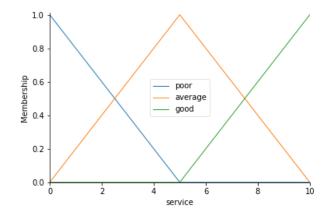

tipping.compute()

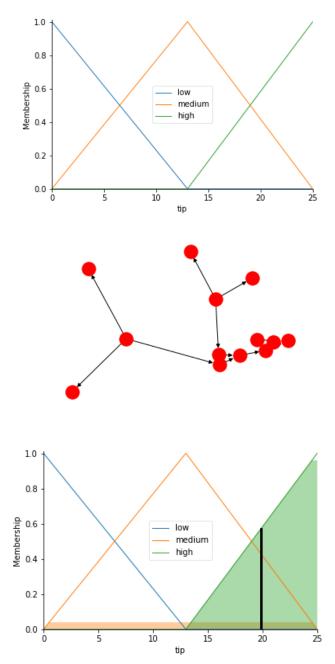

print(tipping.output['tip'])

tip.view(sim=tipping)

## **Output:**

The resulting suggested tip is 20.24%.

### **Result:**

Thus, the Python program for developing a fuzzy controller for the Tipping problem has been executed successfully and the output is verified.
